Objective: to analyze proposed strategies for coping with psychological distress in university students, in the educational context. Methods: integrative review based on original articles published between 2015 and 2020, in English, Spanish or Portuguese, in the following databases: Latin American and Caribbean Health Sciences Literature, Medical Literature Analysis and Retrieval System Online, Base de Dados da Enfermagem, Index da Psicologia, SCOPUS-Elsevier, Cumulative Index to Nursing and Allied Health Literature. Results: 26 articles were considered, with greater publication in 2020 (50%) and 2019 (23.1%); from the Asian continent (46.1%) followed by the American continent (26.9%); referring to students from different training areas, with a quantitative and transversal approach. The systematization of strategies showed: Strategy for the Detection of Psychic Suffering; Strategy for Monitoring and Assessing Psychic Suffering; and Strategy for the Prevention of Psychic Suffering. There was an emphasis on the presentation of several instruments with good psychometric quality and levels of reliability, both for care and for investigations. Conclusion: it was found in the production raised successful strategies for the detection, monitoring and evaluation of psychological distress in students, applicable in health units in school institutions, pointing out guidelines for possible care interventions, promotion of mental health and quality of life.

Descriptors: Psychological distress; Students; Adaptation, Psychological.

Objetivo: analizar estrategias propuestas para el enfrentamiento del sufrimiento psíquico en estudiantes universitarios en el contexto educacional. Método: revisión integradora basada en artículos originales publicados entre 2015 a 2020, en idiomas inglés, español o portugués, en las bases de datos: Literatura Latinoamericana y del Caribe en Ciencias de la Salud, Medical Literature Analysis and Retrieval System Online, Bases de Dados da Enfermagem, Index de Psicologia, SCOPUS-Elsevier, Cumulative Index to Nursing and Allied Health Literature. Resultados: Se consideraron 26 artículos, con publicación mayor en 2020 (50%) y 2019 (23,1%); del continente asiático (46,1%) seguido del continente americano (26,9%); referiendo a estudiantes de diferentes áreas de formación, con abordaje cuantitativo y transversal. A sistematización de estrategias mostró: Estratégia de Detecção do Sofrimento Psíquico; Estratégia de Monitoramento e Avaliação do Sofrimento Psíquico; e Estratégia de Prevenção do Sofrimento Psíquico. Houve destaque na apresentação de vários instrumentos com boa qualidade psicométrica y niveles de confiabilidad, tanto para atendimiento quanto para investigaciones. Conclusión: verificou-se na produção levantada estrategias exitosas de detección, monitoramento e avaliação do sofrimento psíquico em estudantes, aplicáveis em unidades de saúde em instituições escolares, apontando diretrizes para possíveis intervençoes de cuidado, promoção da saúde mental e qualidade de vida.

INTRODUCTION

Entering university brings changes for students, because, while it signals an achievement, it can become a worrying period of greater personal vulnerability, as it distances the young person from the family nucleus and from the previous circle of friends, inserting them in a context that requires new attitudes and responsibilities.\(^1\)\(^2\)

The challenges of adapting to university life associated with emotional difficulties, typical of this stage of the evolutionary cycle, can expose young students to stress, increasing their vulnerability to psychic suffering, triggering psychopathological symptoms that can evolve into mental disorders.\(^3\)

Psychic suffering can be defined as a set of discomforts and difficulties in living with the contradictory diversity of existential meanings, associated with difficulties in establishing plans, defining the meaning of life, or even relating to the feeling of impotence and internal emptiness.\(^4\)\(^5\) As negative consequences of this suffering, with regard to the training process, the following have been reported: absenteeism, requests to cancel enrollments and school dropout.\(^1\)

Considering the epidemiological and educational importance, the relevance of providing collective and individual resources for appropriate care for the early detection of complaints/symptoms in university students emerges, as well as providing follow-up by health professionals in the detected cases, with a view to favoring therapeutic actions immediate steps to intervene as quickly as possible, seeking to minimize suffering and prevent its consequences.\(^6\) In order to provide interventions that are not only based on the biomedical approach, but also on others, which expand the possibilities of modifying and qualifying the conditions and ways of life, focusing on the production of life and health.\(^7\)

Thus, this study aims to analyze proposed strategies for coping with psychological distress in university students, in the educational context.

METHODS

This is an integrative review (IR) developed to obtain theoretical support on the recommended strategies for coping with the psychological distress of university students in the educational context. IR allows analysis and synthesis of scientific production, based on the question of interest of study, showing new methods and concepts, in addition to identifying gaps in knowledge. It is proposed that the IR be prepared following these steps: identification of theme/question for the elaboration of the research; definition of criteria for inclusion and
exclusion of studies; definition of information to be used; analysis and interpretation of results and presentation of the synthesis of knowledge.

The question to be answered by this IR was elaborated based on the PICo strategy, for non-clinical research, where P = Population/Patient/or Problem – Psychic distress in university students; I = Interest – Coping strategies for psychological distress; Co = Context – Universities. Thus, the aforementioned question consisted of: What types of strategies are recommended for coping with the student's psychic suffering in the university context?

The searches were carried out in May and June 2019 and updated in March 2021 in the Latin American and Caribbean Health Sciences Literature (LILACS), SCOPUS, CINAHL, Medical Literature Analysis and Retrieval System Online (MEDLINE), databases specialized bibliographic databases in the area of Nursing (BDENF) and Psychology (INDEX PSICOL). These databases were chosen for the extent of scanning they allow, including internationally, specialized and multidisciplinary productions.

In the searches, Descriptors in Health Sciences (DeCs) and Medical Subject Headings of the U.S. were used. National Library of Medicine (Mesh) controlled and combined with Boolean operators: “Sofrimento Mental/Suffering Mental” OR “Saúde Mental/Mental Health” AND “Avaliação/Evaluation” OR “Intervenção/Intervention” OR “Atendimento/Attendance” AND “Estudantes/Students” OR “Universidade/University” OR “Faculdade/College”.

The inclusion criteria were: original articles, available in full, published in English, Spanish or Portuguese, in Brazilian and international journals, between January 2015 and December 2020 and that had content to answer the previously defined study question. Articles that were repeated in the different databases used were excluded.

The articles found were analyzed after careful reading of titles and abstracts and those selected were submitted to full reading and the characterization of the corpus of analysis was carried out.

The presentation of the results was carried out in a descriptive way, and the content identified in the included articles was systematized and grouped into categories allowing a better understanding of the data.

RESULTS

By combining the descriptors, 2647 publications were identified. After analyzing the titles and applying the inclusion criteria, 2607 were excluded and one per repetition, leaving 39 articles. By analyzing the abstracts, nine publications were excluded, forming a set of 30 articles. Of these, four articles were excluded, as two could not be accessed in full, one did not
refer to university students and one did not answer the guiding question, thus comprising the final sample of 26 articles (Figure 1).

**Figure 1.** Stages in the selection of articles on recommended strategies for coping with psychological distress in university students. Brazil, 2020.

Regarding the characteristics of the publications of the 26 studies included in this IR, Table 1 shows the universal distribution of countries of origin, coming from countries on five continents, with a predominance of the Asian continent (one from Jordan, one from India, one from Malaysia, one from Pakistan, two from South Korea, one from Indonesia, one from the Philippines, one from the UAE, two from China and one from Iran), followed by the American continents (one from Canada, two from the USA, one from Trinidad and Tobago and three from Brazil), European (one from Italy, one from the United Kingdom and two from Germany), from Africa (two from Ethiopia) and from Oceania (one from Australia).

Regarding the area of knowledge of the journals in which they were published, most were linked to Mental Health. The prevailing language in which these articles were published...
was English, and the year with the highest concentration of publications was 2020, with a higher frequency of research with students from areas other than the Health area. In turn, in the health area, 23% were linked to the medical course, 14% to psychology, 6% to nursing and/or midwifery and 3% to medicine and engineering (Table 1).

As for the objectives, the included studies could be equally subdivided into those that mainly proposed to study *aspects related to the occurrence of psychological distress* (OPD) (50%), and those that turned to work on *coping strategies for this condition* (CSPD) (50%). Most of the studies used a quantitative research approach (92%), with 50% of these studies being cross-sectional and descriptive (Chart 1).

**DISCUSSION**

The instruments mentioned in the studies considered were characterized as having good psychometric quality and levels of reliability, making it possible to verify their contributions to the purposes established in each researched situation.

Among the successful strategies for coping with the psychological distress of university students, those that make it possible to promote the search for support by university students5,12,18. The coping strategies used confirmed that early detection and effective intervention can prevent future diseases12,16,22.

Among such strategies are the offering of Mindfulness courses13,15,20,27,33. Mindfulness is a secular group skills and training program based on the textbook *Mindfulness: A Practical Guide to Finding Peace in a Frantic World*, adapted for college students36.
This program is a comprehensive mental health strategy, including offering this type of intervention openly to students, separate from specific mental health services, and is seen as a useful complement to clinical interventions that can help students accept or set aside aspects of stress factors that are uncontrollable, helping to maintain good mental health in university students.

Another practice, also related to Mindfulness, Yoga with a focus on breathing, maintains attention and awareness and reduces stress in university students.

With the aim of improving students’ well-being and reducing symptoms of psychological problems, analytic psychodrama groups held periodically have proved to be a technique that can help students feel more confident.

Spiritual support and self-compassion were also listed as important strategies, and with better spiritual health and feelings of self-compassion, there is a tendency for weaker depression, being less affected by stress and burnout and more likely to be involved in health promotion behaviors. Compassion can be strengthened through the practice of mindfulness.

Welcoming and listening can function as a temporal operator of interventions for the comprehensive health care of students who manifest symptoms of mental distress, welcoming them in a timely manner, but with no rush, establishing the necessary time to help them find tools to face their impasses.

And for students who might be reluctant to seek support through traditional face-to-face mental health services, web-based programs have been identified, which offer the opportunity to support vulnerable college students who are unlikely to seek support otherwise. These tools guide how to understand or monitor behavioral signs and indicators of their mental health states and suggest appropriate actions for their improvement.

The intervention carried out over the internet proved to be easy to apply and cost-effective, with effective support for overcoming procrastination, which may be related to generalized anxiety disorder or depression.

In addition to these proposals, a set of five strategies was suggested, among them relaxation to use one of the five senses and calm the mind; recognize the situation before it gets worse (self-knowledge); think of a solution that helps to stop the situation and refresh the mind; sharing of emotions and socialization.

The formation of support networks was presented as a fundamental strategy for overcoming obstacles in student life, maintaining a frank and open dialogue about problems.
and collectively building strategies to overcome them, forming bonds between students, teachers and technicians\textsuperscript{21}.

It is essential to recognize what is already done daily in the school environment and what the territory where the school institution is inserted has to offer as a resource to contribute to the management and control of this disease.

Some mental health actions have been carried out without the professionals even realizing them in their practice, such as support actions: discussion of cases, joint care or not; interconsultation; joint construction of therapeutic projects; Permanent Education; interventions in the territory and in the health of population groups and the community; intersectoral actions for prevention and health promotion; and, discussion of the teams’ work process\textsuperscript{7}.

In addition, system-wide initiatives that include university administrators, instructors, counselors, academics, nurses, and other health professionals in promoting mental health that combine awareness-raising efforts that emphasize the benefits of seeking services have been indicated as promising approaches to address the underutilization of mental health services or even the creation of them\textsuperscript{10,11}.

It also brings the importance of carrying out and deepening research and works to determine academic training programs, evaluation systems and support for university students\textsuperscript{10}.

It is up to higher education institutions to facilitate this transition from the context of distancing from family and friends and acquiring greater autonomy and independence, from the high school to higher education model, promoting the creation of contexts that aim at the total integration of young people for the continuation with quality at the university until the conclusion of the course, being concerned with knowing and promoting the quality of life and health of its students\textsuperscript{6,22}.

The results of this IR support the recommendation to provide special attention to students, through preventive care strategies and monitoring/assessment of students’ psychological distress and mental health promotion in the school context, as well as ensuring relevant therapeutic care in partnership with specialized health services/professionals, aiming at networking, with the direct and participatory involvement of the entire academic community.

The studies surveyed brought fundamental contributions to constitute strategies and services dedicated to the care of mental health and quality of life of university students, which minimize the risks of developing psychological distress.
In the subsidiary findings of the present IR, it was possible to relate instruments used to detect signs and symptoms of psychic suffering and related mental disorders, and those recommended for monitoring and evaluating the mental health situation before and after interventions to face this problem.

The Hamilton Rating Scale for Depression (HAM D)\textsuperscript{26} was built in the 1960s to be used exclusively in patients previously diagnosed with depressive-type affective disorder, due to the design and choice of its items, which serve to identify the severity of depressive symptoms, and not their existence.\textsuperscript{37}

The General Health Questionnaire (GHQ12) detects non-severe psychiatric illnesses\textsuperscript{38} and was used together with the Medical Student Stressor Questionnaire (MSSQ 40) with medical students\textsuperscript{10}.

The Hospital Anxiety and Depression Scale (HADS) developed in the 1980s with the purpose of identifying cases (possible or probable) of mild anxiety and/or depression disorders\textsuperscript{39} was used to screen for depression and anxiety in medical students\textsuperscript{32}.

The Mini International Neuropsychiatric Interview (Mini), version 5.0.0, compatible with the DSM-IV criteria, is a brief diagnostic interview attributed to use in clinical practice and research in primary care and psychiatry, and was also used with medical students to check for psychiatric disorders\textsuperscript{22}.

Regarding the questionnaires, we found those adapted on perception, knowledge and attitude\textsuperscript{35} and others such as: Alcohol Use Disorders Identification Test (AUDIT-C), used to assess the drinking habit\textsuperscript{32}; Godin-Shephard Leisure-Time Physical (GSLTPA) used to assess exercise habits among college students\textsuperscript{32} and the Pittsburgh Sleep Quality Index (PSQI), used in medical\textsuperscript{32} and nursing\textsuperscript{23} students to assess sleep quality.

The Maslach Burnout Inventory (MBI) is an instrument used exclusively for the assessment of Burnout Syndrome, not taking into account the antecedent components and consequences of its process\textsuperscript{40}, this same scale was used and academic burnout explained the relationship between the academic demands and depression in medical students\textsuperscript{12,32}.

The Perceived Stress Scale (PSS)\textsuperscript{12,34} is an instrument applied to assess the perception of stress and the individual's perception of how unpredictable and uncontrollable the life events experienced in the last month seem, and it was used in medical students - Perceived Medical School Stress (PMSS)\textsuperscript{12} and in obstetrics students\textsuperscript{34}.

The Stress Scale (PSS) stands out for the brevity of the instrument, which favors its application in conjunction with other measures, being used together with the Depression, Anxiety and Stress Scale - Short Form (DASS 21) and the Traumatic Life Events Questionnaire.
(TLEQ)\textsuperscript{13} in psychology course students to investigate the effectiveness of interventions carried out on the Internet to reduce stress with and without a history of trauma, showing that such interventions teach skills to focus and consequently reduce stress\textsuperscript{13} and used together to other scales to assess the effectiveness and acceptability of an internet-based intervention for procrastination\textsuperscript{20}.

The Depression, Anxiety and Stress Scale (DASS)\textsuperscript{13,18,31} can be used to measure stress through questions in which participants indicate the degree to which they experience each of the symptoms described in the items during the last week.

Regarding student procrastination, the scales used were Irrational Procrastination Scale (IPS), Generalized Anxiety Disorder Scale (GAD 7), World Health Organization Well-Being Index (WHO 5) and as potential mediators the Scale of Susceptibility to Temptation (STS) and the General Self-Efficacy Scale (SWE) measuring sensitivity to distractions and immediate gratification and perceived self-efficacy\textsuperscript{20}.

Another scale that has been identified as a reliable and adequate measure to assess the symptoms of generalized anxiety in different clinical contexts is the Generalized Anxiety Disorder 7 (GAD-7)\textsuperscript{29}. The WHO 5 has good diagnostic properties and was used to assess subjective psychological well-being\textsuperscript{20}.

The Kessler Scale for Psychological Distress (K)\textsuperscript{41}, designed to assess non-specific depressive and anxious symptoms in the last 30 days, is an instrument that identifies distress, being used in the K6\textsuperscript{11} version to understand the reasons why psychology students underuse services of mental health and in the K10 version, along with the psychometric test of the Mental Health Continuum (MHC)\textsuperscript{24} model, with students from different areas to help them reflect and improve their mental health.

In a study designed to assess the prevalence of mental distress, perceived need for professional mental health care and barriers to providing services to university students, the Self-Reported Questionnaire (SRQ-20) and Barriers to Access to Care Assessment (BACE-30) scales were used, showing that they are useful tools to address the disparity between mental suffering and scarcity of care\textsuperscript{30}.

The Self-Compassion Scale (SCS)\textsuperscript{27,32} was used to measure students’ self-compassion, being a valid instrument for health research and intervention environments, used with the Center for Epidemiologic Studies Depression (CESD) scale, to measuring current levels of depression and the Maslach Burnout Inventory Student Survey (MBISS) suggesting that, although students with a high level of self-compassion may feel drained by academic demands,
this would not progress to depression, i.e., self-compassion has shown the possibility of moderate the development of depression in the academic environment. 

And with psychology students, the SCS was used in conjunction with the Five Facet Mindfulness Questionnaire (FFMQ), which is a mindfulness measure commonly used to assess change before and after mindfulness-based interventions revealing that this practice can improve empathy and self-compassion helping students' mental health.

Like the FFMQ, the Mindful Attention and Awareness Scale (MAAS) was also used to assess mindfulness, determining the frequency with which each situation occurs.

With nursing students, to assess the reasons for stress in the university environment and the repercussions on the quality of sleep and life, the Assessment of Stress in Nursing Students (ASNS) and Pittsburgh Sleep Quality Index (PSQI) instruments were used, pointing out that stress factors were associated with poor sleep quality and changes in quality of life.

The Clinical Outcome Routine Evaluation – Outcome Measure (CORE-OM) is an European self-report instrument to measure mental health in adults and is adapted for more than 20 countries, being commonly used in hospital clinical contexts, occupational and educational, as well as in the assessment of the quality of mental health services.

The Global Rating Scale (GAS), used with the CORE-OM, serves to assess the general functioning of a subject during a specified period of time, in a continuum of psychological or psychiatric illness.

For screening for major depressive episodes, the Patient Health Questionnaire-9 (PHQ9) scale was used.

Summarizing, the instruments listed in this review study proved to be tools to support the early detection of psychological distress, as well as to monitor and evaluate the detected cases.

**CONCLUSION**

This review made it possible to draw an overview of the possibilities of coping with the psychic suffering of students in a university context, also helping to relate different instruments for the detection, monitoring and/or evaluation of this condition, applicable both in care provided in health services of educational institutions and in research on this topic.

As limitations, there is the reduced number of studies referring to coping strategies, which points to the need for more research in this area.

In addition, in a universal and relevant way, psychological distress in university students has been shown to be an emerging public health problem and that interventions to face it,
whether they are mental health promotion, evaluation and monitoring or treatment, should be adopted as a priority by school institutions in partnership with extramural health services.
